

Fine chemicals from beet pulp and molasses

Сгор	Sugar Beet Beta vulgaris subsp. vulgaris cultivar Altissima
Croppart	Roots / Tubers
Application area	Fine chemicals
Status	Research stage
Relevant plant compounds	Sugars
	Cellulose
	fibres

Description

The AFTERBIOCHEM project wants to develop a chemical platform for transforming sidestreams from the sugar industry – mainly beet pulp and molasses as well as non-food biomass – into bio-molecules and derivatives of industrial interest. This will increase the economic and environmental sustainability of the sugar beet industry at a time when it faces severe competitive pressures. Although the project will initially target sugar beet processing plants, the platform will be sufficiently flexible to be able to adapt to alternative feedstocks.

Pros and cons

Upgrading the value of a very important residual stream in Europe

Creating sustainable chemicals

Used conversion methods

Mechanical-Physical processes

Fiber separation

Extraction

Biochemical processes

Aerobic/ Anaerobic fermentation
